

CIS170 Project 10

In this project, you will create a simple inquiry program from scratch. In the last project, you wrote an RPG interactive program that interacted with some screens that had been partially designed for you.

Recall that an interactive “inquiry” program is one in which the user enters, via an input screen, a piece of data that is critical to retrieving corresponding data from an existing database file. If that piece of data is incorrect, the retrieval of the corresponding database data will be unsuccessful, and the user will need to be alerted that an error has occurred.

Choose one of the following files to work with:

BIDS, WUEXAMP, or WUHRLYP

These files are in the RPGIV_5THS library, which is on your library list. To examine the definitions of these files, use either RDi or PDM to “drill into” **QDDSSRCW** in the **RPGIV_5THS** library.

Familiarize yourself with the contents of the file by using the RUNQRY command, for example:

```
RUNQRY QRYFILE ( (xxxxxxxx) )      Jot down some data so that you can refer to this while  
                                     testing your program
```

Design a two-screen inquiry application.

Using the RDi Screen Designer:

Screen #1: an entry area for the user to enter in whatever KEY data is appropriate for the file you chose. If the KEY data entered is “bad” then the user should be alerted that an error has occurred, since the corresponding data cannot be retrieved. (Note that there will not need to be two separate CHAIN operations in this application since you are only accessing one database file) Also include:

- The current date
- A title for your application
- The user id
- Show that F3 can be used to exit the application

Screen #2: will only be displayed if the retrieval process was successful, it will display the data retrieved from the database file.

- Display the data in an attractive easy to read layout.
- Be sure to include appropriate editing of numeric items.
- The items are output only.
- Also, on this screen the user should be able to press either F3 to exit the application entirely, OR press F12 to return to the first screen.
- The user should also be able to simply press enter to return to the first screen.

--- continued on next page ---

Code the RPG Program that works in tandem with the above screens:

Inside the loop, insert logic for the following:

Use the input field from the first screen to randomly retrieve the corresponding record from the file (CHAIN)

If the chain is good:

Display the second screen (remember that while on the second screen, your user should be able to press either enter or F12 or enter to return to the first screen)

If the chain is not good, turn on the "bad" indicator so that when the first screen is redisplayed a message will be displayed to alert the user.

Test your program with good and bad key data. Be sure that F3 works – it should totally exit the program.

Email me when you are ready to have the program evaluated, and attach screen captures of RDi in use for the design of both of your screens.
