Assignment Instructions

Week 5 Project, Part 1: Add JavaScript to Your Home Page

Before You Begin

Complete this week's reading and review the related videos before starting.

Last week, you made your homework home page more responsive. This week, you will build on that work by adding JavaScript that responds to user actions and changes what appears on the page.

1. Create an External JavaScript File

Create a separate JavaScript file and connect it to your homework home page using a <script> element.

Refer to **Moving the Code to a Script File**, pages **455–457**, for guidance.

Upload both your revised HTML file and your JavaScript file to the student server. Make sure the path in your <script> element matches the JavaScript file's location.

2. Create Three Functions Connected to Different Events

Write at least three functions in your external JavaScript file. Connect each function to a **different type of event**.

For example, you could have a function run when a visitor:

- Clicks an element.
- Moves the pointer over an element.
- Moves the pointer away from an element.

You may use these events or choose others from **Table B-1 on page 458**. Each function should produce a result you can demonstrate and explain.

3. Change Visible Page Content

At least **one of your three functions** must change visible content on your homework home page. For example, it could replace a message or update a paragraph when a visitor interacts with the page.

Refer to **Interacting with the Page** in Appendix B for examples.

4. Add Another JavaScript Feature

Add one additional JavaScript function that demonstrates something else you learned this week.

You might use a variable, perform a calculation, or use conditional logic to display different messages. Choose something you understand well enough to explain.

Test Your Work

Open your published homework home page in a browser and check that:

- Your external JavaScript file loads correctly.
- Each of the three event types triggers its intended function.
- At least one function changes visible page content.
- Your additional JavaScript feature works.
- Your existing navigation and responsive layout still work.

Save and test frequently. Making one change at a time will help you identify problems.

Submit Your Project

Submit the following through the **Week 5 Project** assignment link in Blackboard:

1. **The URL to your updated homework home page** on the student server.
2. **A brief summary of your JavaScript features**, identifying the three event types, the visible content change, and your additional function.

Give yourself time to experiment, and please reach out if you get stuck. I am happy to help!

Front End:

Summary of features

Three Functions Connected to Different Events

mouseover (highlightBox()): Moving the mouse point over the .col1 container changes the border color to yellow, deepends the shadow, and updates the status indicator text.

mouseout (resetBox()): Moving the mouse pointer away restores the cyan border and resets the status message.

click (toggleWelcomeMessage(): Clicking the “Change Content” button toggles and swaps the visible text inside the welcome paragraph.

Change Visible Page Content

toggleWelcomeMessage(): This function uses DOM manipulation to replace the initial description text with a confirmation message indicating active DOM manipulation, complete with a button label state toggle.

Add Another JavaScript Feature

displayGreeting: Use new Date().getHours() and multi-branch conditional logic (if/else if/else) to evaluate the time of day and render a contextual greeting based on the time of day. I use document.querySelectorAll() that displays the count of the projects in my directory.
